## 5. Function Description

### 5.1 Device operation

When L/R=H, MODE1=H, MODE2=H, MODE3=H, EVEN=L, and SGOFF=L, the STV1 start pulse input is sensed on the rising edge of CPV and stored in the first stage of shift register, which makes the first scan signal output from the OUT1 pin. While stored data is transferred to the next stage shift register on the rising edge of next CPV, new data of STV1 is sensed and stored simultaneously.

The output pin (**OUT1 to OUT480**) supplies VGH voltage or VGL voltage to the LCD panel depending on the data stored in the shift register. For normal operation, a VGH voltage is outputted one by one from OUT1 to OUT480 in synchronization with CPV pulse.

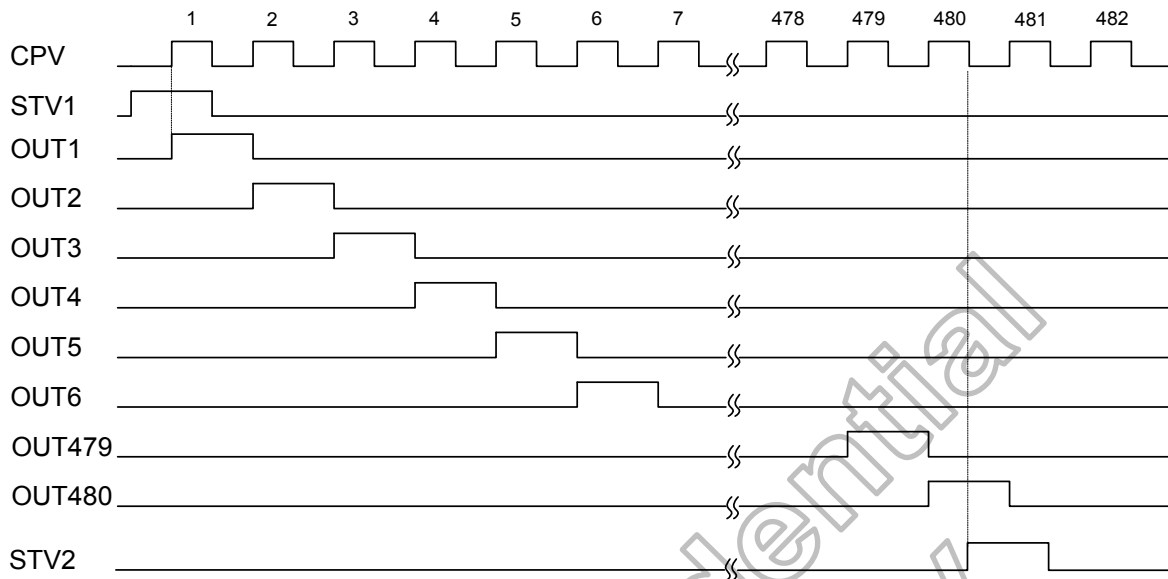

After 480<sup>th</sup> CPV rising edge, the STV2 goes up to high level on the 480<sup>th</sup> falling edge of CPV and goes down to low level on the 481<sup>st</sup> falling edge of CPV. This STV2 output signal becomes the STV1 start pulse input of next cascaded gate driver.

Generally, GPM (**Gate pulse modulation**) is used to reduce the influence of the feed through caused by the gate driver output falling. However, GPM consumes much power because of the large parasitic capacitance over VGH power trace. The HX8678-C supports slow gate off function to replace GPM function. When SGOFF=H, CPV=L and OE=L, the output NMOS pulls the scan line to VGL level, and VGN can control the falling rate of the output voltage to obtain slow gate off function. When OE=H, the corresponding output channels are drove to VGL level regardless of CPV state and VGH controls the falling rate. It can reduce the feed through influence and the power consumption is much lower than GPM.

The HX8678-C is embedded with a power off reset circuit. When VDD drops below the threshold voltage  $V_{POFF}$ , the internal /XAO will be "L" regardless of the external /XAO input, it makes all outputs rise to VGH level to reduce possible power off image residue.

**E. Example of input/output timing (MODE1=H, MODE2=H, MODE3=H, L/R=H, EVEN=L, SGOFF=L with OE & /XAO)**

### 5.2 Device power level

The logic levels of CPV, L/R, OE, /XAO, MODE1, MODE2, MODE3, EVEN, SGOFF, STV1 and STV2 have to swing between VDD for “H” and VSS for “L”.

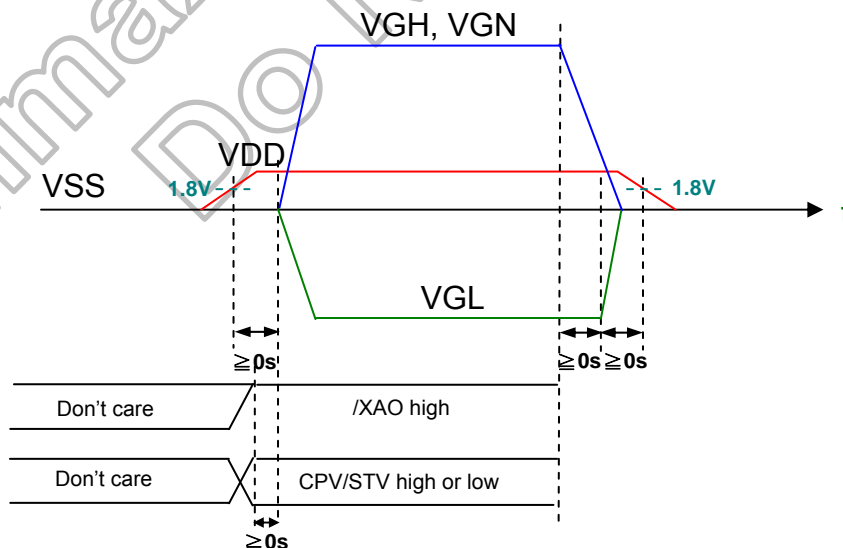

### 5.3 Power on/off sequence

The power on/off sequence need be followed as shown below.

When power on, VGH/VGL can start to be turned on after VDD reaches 1.6V. When VGH/VGL start to be turned on, CPV and STV should be not floating, and /XAO should be at VDD level or floating. The other control signals have no timing limitation.

When power off, VGH, VGN/VGL must start to be turned off before VDD drops to 1.6V. If the possible power off image residue is not concerned or the backlight is turned off in advance to shadow the possible image residue, there is no power off sequence limitation.

When power on: VDD → VGH, VGN/VGL  
 When power off: VGH, VGN → VGL → VDD
